Household Water Quality
Prince George County 2009-2015

The Virginia Household Water Quality Program provides affordable water testing and education through local Extension offices to the 1.7 million Virginians who rely on wells, springs or cisterns for their household water supply.

What’s in your water?

Municipal water supplies are regulated under the Safe Drinking Water Act, which mandates routine testing and treatment. Maintenance and testing of private water supplies (wells, springs and cisterns) is the responsibility of the owner. Virginia Cooperative Extension offers water testing and education for private water supply users across the state.

Drinking water clinics are held in county Extension offices each year. Here’s how it works:

**#1 Kickoff Meeting**
 Participation is voluntary and open to anyone with a well, spring or cistern. Participants pick up a sample kit and receive instructions about how to collect the samples from their household tap and where and when to drop off their samples.

**#2 Sampling**
 Following directions carefully, participants collect their samples and complete a short questionnaire. Samples are dropped off locally, so shipping is unnecessary. We coordinate getting the samples to Virginia Tech’s campus for analysis.

**#3 Analysis**
 Samples are analyzed for total coliform and E. coli bacteria, nitrate, lead, copper, arsenic, fluoride, sodium, hardness, iron, manganese, total dissolved solids, pH, and sulfate. The cost for one sample kit in 2015 was $50. Confidential results are prepared and returned to the Extension office.

**#4 Results**
 Results are returned to participants and explained at a local interpretation meeting. Information is provided about addressing water quality problems, routine care, and maintenance of private water supplies.

Water systems in Prince George County (2009 - 2015)

148 samples analyzed
Serving 326 people
Well depth: 20 to 351 feet
Well age: 5 to 77 years

**Systems**
- Drilled and bored wells were both common.
- Eighteen percent of participants did not know what type of system they had.

**Treatment**
- Only 27% of participants reported having treatment devices installed. The most common devices were sediment filters and water softeners.

Contaminants in water may be health-related (e.g., bacteria) or a nuisance (e.g., hardness causing scale) and can come from a variety of sources.

Some contaminants originate from geology, the sediment or rock where the water is stored. Others are a result of land usage or activities on the earth's surface, such as lawn fertilizer, animal waste, or chemical spills.

Proper construction of a well can protect household water quality by preventing surface water, which may carry many contaminants, from entering the groundwater supply. Wells should be constructed with proper casing, grout seal, and a sealed well cap. Contamination sources, such as livestock and septic systems should be at least 50 feet away from the well head.

Treatment devices and plumbing components can also influence water quality by adding contaminants or changing water chemistry.

Where do contaminants come from?

*Landuse and nearby activities*

*Plumbing materials and water treatment*

*Household water quality*

*Hydrogeology*

Household water quality in Prince George County: Common Contaminants

The most common contaminants found in household water in Prince George County were, total coliform bacteria, low pH, lead, copper, and E. coli.

Total coliform bacteria presence is an indication that surface water may be entering a well and other more harmful microorganisms may be present. Total coliform were present in 75% of Prince George samples. E. coli were found in 11% of Prince George samples and are a sign that human or animal waste is entering the water supply.

Low pH (<6.5) can occur naturally in parts of Virginia geology. pH below 6.5 was found in 64% of samples. Although not a concern in itself, low pH can be a driver of how corrosive the water is and can result in metals such as copper and lead leaching into the water from plumbing components. Lead was found in first draw samples exceeding 0.015 mg/L in 30% of samples, and copper exceeding 1 mg/L in 27% of samples.

For information about other common contaminants, please visit our Resources Page.

Special thanks to the residents of Prince George County who participated in the Virginia Household Water Quality Program drinking water clinics held in 2009-2015. Extension agent Scott Reiter, among other partners, was instrumental in the program's success.
